

• Live on Arc • settled in USDC

Arc Pump

Pay-per-call payments for AI agents.

The payment rail where autonomous agents pay per request in USDC on Arc — metered, capped, settled and verified on-chain. No subscriptions, no humans.

THE PROBLEM

AI agents can't pay for what they use.

Agents are exploding — and they increasingly need to buy things on their own: APIs, data, compute, tools. But today's payment models were built for humans:

- **Subscriptions & API keys** don't fit a machine that makes one call, once.
- **Cards & human checkout** need a person in the loop — the opposite of autonomy.
- There's **no clean, metered, per-request rail** for agent-to-service payments.

THE SOLUTION

Pay-per-call, in USDC on Arc.

An x402-style rail: an agent hits a paid resource, gets a `402 Payment Required` + an invoice, and its wallet pays that invoice in native USDC through an on-chain router. The service verifies the payment on-chain, then serves the response.

- **Metered** — pay exactly per request, down to a cent.
- **Bounded** — every agent runs under a per-call cap and a total budget.
- **Verifiable** — every payment is a real, invoice-bound tx on Arc.

HOW IT WORKS

Three steps.

01 · Request

402 + invoice

Agent calls the resource; the service replies with a price, an invoice id, and where to pay.

02 · Pay

`router.pay(...)`

The agent's Circle wallet pays the invoice in native USDC through the on-chain PaymentRouter — within its caps.

03 · Unlock

verified → 200

The service checks the router in one view call (invoice + recipient bound), then serves the data. One payment, one call.

NOT A MOCKUP

It's live, and it's real.

On arcpump.com/pay anyone can click **"Run it"** and watch a real AI agent pay 0.01 USDC on Arc to unlock a resource — step by step, with the on-chain tx. Or connect a wallet and pay it yourself.

402→200 **live**

FULL FLOW, ON-CHAIN

capped

LEDGER OF EVERY PAID CALL

PER-CALL + BUDGET GUARDRAILS

BUILT ON

The stack.

- **PaymentRouter** — a small Solidity contract on Arc that binds each payment to an invoice + recipient (native USDC has no memo). [0x42bCE0...28ff](#)
- **Circle Programmable Wallets** (MPC) — agents sign autonomously; no raw private key on any server.
- **Native USDC on Arc** — payments are plain value transfers, final in ~1 second.
- **Next.js + Cloudflare Workers** — the landing, the service wrapper (402), and the pay-client SDK.

TRY IT

Agents paying for what they use.
